

# Injuries among Seniors

Every four minutes in Ontario, at least one senior visits an emergency department and every 20 minutes at least one senior is hospitalized with an injury. Injuries are more common among females than males.

## Results

In Ontario, during the 2005/06 fiscal year, there were a total of 150,470 emergency department visits and 30,478 hospitalizations among seniors 65 years of age and older. For emergency department visits, injuries peaked among females 65-66 and 77-83 years and males 65-70 years of age (Figure 1). For hospitalizations, injuries soared among females 76-90 years and peaked among males 75-85 years of age.

Among seniors, the overall provincial rate of injury for emergency department visits was 9,130.9 per 100,000 population and for hospitalizations was 1,762.0 per 100,000 (Table 2). The highest rates were seen among those 85 years of age and older (Table 3).

Unintentional falls were by far the leading external cause of injury among seniors, accounting for 59% of all emergency department visits and 79% of hospitalizations due to an injury. The most common type of fall was a slip or trip on the same level followed by stair-related falls.

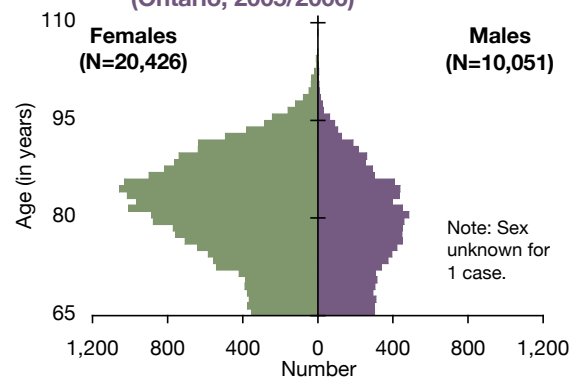

About 80% of seniors who visited an emergency department were discharged to their place of residence and 18% were admitted to the hospital where they were seen. For hospitalized cases, about 42% were discharged home (including discharges home with support services), 27% were transferred to a long-term care facility, and 22% were transferred to another facility that provides inpatient hospital care. Fewer than 1% of seniors died after arrival in the emergency department and almost 8% died after hospital admission. The 30,478 hospitalized cases accounted for more than 300,000 days in acute care hospitals with an average length of stay of 9.9 days.

By region, the lowest overall injury rates were observed in the Toronto region and the highest rates were seen in the North region (Table 2). This pattern was seen for both emergency department visits and hospitalizations.

## Discussion

This Compass highlights patterns of injury for emergency department visits and hospitalizations among seniors in Ontario. Other Ontario and national analyses have also examined patterns of injury and falls among seniors.<sup>1-5</sup>

A recent Ontario report identified that seniors represent over one-tenth of all visits to an emergency department and two-fifths of admissions to hospital due to an injury.<sup>1</sup> The magnitude or frequency of injuries among Ontario's seniors represents only one aspect of the injury issue. These injuries are also associated with substantial economic costs.

A report released in 2006 by SMARTRISK highlights costs of falls among seniors as an important area of concern.<sup>6</sup> Falls among those 55 years of age and older accounted for \$962 million, almost half of all costs related to falls or about 17% of the total economic costs for injury in the province.<sup>6</sup> These statistics become even more alarming when the age structure of Ontario's population is considered. Seniors represent about 13% (or about 1.6 million) of Ontario's population and this proportion is expected to almost double to nearly 25% (or about 3.5 million) by 2031.<sup>7</sup>

## Managing the risk

Check the online Catalogue at the Ontario Injury Prevention Resource Centre for examples and details of best practices for older adults:

### Falls

- ❖ No Falls! No Fear! Falls Prevention Project
- ❖ Stay on Your Feet
- ❖ Tai Chi and Computerized Balance Training

### Motor and other road vehicle

- ❖ DriveABLE Assessment Centres
- ❖ Florida Elder Roadway User Program

**Key factors emerging from these best practices include using multifactorial/multi-sectoral interventions and selecting the appropriate approaches for the setting or target population. Interventions should act on risk factors, such as history of falls, physical or cognitive impairment, low body mass index, use of multiple medications, and home hazards.**

## Methods

Emergency department data were obtained from the National Ambulatory Care Reporting System and acute care hospitalization data were obtained from the Discharge Abstract Database at the Canadian Institute for Health Information for the 2005/06 fiscal year. All cases for seniors 65+ years of age were included in this analysis. Causes of injury were classified according to available International Classification of Diseases, 10th revision (ICD-10) codes. Note that some persons were seen in an emergency department and then admitted to hospital; however, persons can be admitted to hospital without visiting an emergency department. Deaths occurring outside of the hospital setting are not included in this analysis. Regions were defined according to place of residence using the Ontario Ministry of Health Region Codes.
